

# A Type Theory with Native Homotopy Universes

Robin Adams<sup>1</sup> and Andrew Polonsky<sup>2</sup>

<sup>1</sup> Universitetet i Bergen

<sup>2</sup> University Paris Diderot

We present a type theory  $\lambda \simeq_2$  with an extensional equality relation; that is, the universe of types is closed by reflection into it of the logical relation defined by induction on the structure of types.

The type system has three universes:

- The universe **Prop** of *propositions*. An object of **Prop** is called a *proposition*, and the objects of a proposition are called *proofs*. There is a proposition **1**, which has a unique proof  $*$ .
- The universe **Set** of *sets*.
- The universe **Groupoid** of *groupoids*.

For each universe  $U$ , we have an associated relation of equality between  $U$ -types  $\simeq$ , and between objects of  $U$ -equal types  $\sim$ . The associated rules of deduction are:

$$\frac{A : U \quad B : U}{A \simeq B : U} \quad \frac{a : A \quad e : A \simeq B \quad b : B}{a \sim_e b : U^-}$$

where  $U^-$  is the universe one dimension below  $U$ . Thus:

- Given two propositions  $\phi$  and  $\psi$ , we have the proposition  $\phi \simeq \psi$  which denotes the proposition ‘ $\phi$  if and only if  $\psi$ ’. If  $\delta : \phi$ ,  $\epsilon : \psi$  and  $\chi : \phi \simeq \psi$ , then  $\delta \sim_\chi \epsilon = \mathbf{1}$ . (*Cf* In homotopy type theory, any two objects of a proposition are equal.)
- Given two sets  $A$  and  $B$ , we have the set  $A \simeq B$ , which denotes the set of all bijections between  $A$  and  $B$ . Given  $a : A$ ,  $f : A \simeq B$  and  $b : B$ , we have the proposition  $a \sim_f b : \mathbf{Prop}$ , which denotes that  $a$  is mapped to  $b$  by the bijection  $f$ .
- Given two groupoids  $G$  and  $H$ , we have the groupoid  $G \simeq H$ , which denotes the groupoid of all groupoid isomorphisms between  $G$  and  $H$ . Given  $g : G$ ,  $\phi : G \simeq H$  and  $h : H$ , we have the set  $g \sim_\phi h : \mathbf{Set}$ , which can be thought of as the set of all paths between  $\phi(g)$  and  $h$  in  $H$ .

We have reflexivity provided by the following typing rules:

$$\frac{A : U}{1_A : A \simeq A} \quad \frac{a : A}{r_a : a \sim_{1_A} a}$$

The relation  $\sim_{1_A}$  thus behaves like an equality relation on each type  $A$ .

The introduction and elimination rules for  $\simeq$  ensure that  $A \simeq B$  is the type of equivalences between  $A$  and  $B$ :

$$\frac{e : A \simeq B \quad a : A}{e^+(a) : B} \quad \frac{e : A \simeq B \quad b : B}{e^-(b) : A}$$

$$\frac{a : A \quad b : B \quad e : A \simeq B}{e^=(a, b) : (a \sim_{1_A} e^-(b)) \simeq (e^+(a) \sim_{1_B} b)}$$

$$\frac{\begin{array}{c} \Gamma, x : A \vdash b : B \\ \Gamma, y : B \vdash a : A \\ \Gamma, x : A, y : B \vdash e : (x \sim_{1_A} a) \simeq (b \sim_{1_B} y) \end{array}}{\Gamma \vdash \text{univ}([x : A]b, [y : B]a, [x : A, y : B]e) : A \simeq B}$$

Each universe is itself an object of the next universe:

**1 : Prop : Set : Groupoid**

and we have the following definitional equalities:

$$\phi \sim_{1_{\text{Prop}}} \psi \stackrel{\text{def}}{=} \phi \simeq \psi, \quad A \sim_{1_{\text{Set}}} B \stackrel{\text{def}}{=} A \simeq B$$

The following computation rules also hold in  $\lambda \simeq_2$ .

**TODO**

We therefore note the following features of  $\lambda \simeq_2$ :

- Univalence holds definitionally — an equality between types  $A \simeq B$  is exactly (definitionally) the type of equivalences between  $A$  and  $B$ .
- Transport respects reflexivity and composition definitionally.

This type theory has been formalised in Agda, using the method of the system **Kipling** from McBride [5]. The method ensures that, if  $s$  and  $t$  are definitionally equal expressions in  $\lambda \simeq_2$ , then  $\llbracket s \rrbracket$  and  $\llbracket t \rrbracket$  are definitionally equal objects in Agda.

We have

- a type **data**  $Cx : \text{Set}_1$
- functions  $[_]C : Cx \rightarrow \text{Set}_1$ 

$$\begin{aligned} \text{EQC} &: \forall \Gamma \rightarrow [\Gamma]C \rightarrow [\Gamma]C \rightarrow \text{Set} \\ \text{EQC}_2 &: \forall \{\Gamma\} \{a_1 \ a_2 \ b_1 \ b_2 : [\Gamma]C\} \rightarrow \\ &\quad \text{EQC } \Gamma \ a_1 \ a_2 \rightarrow \text{EQC } \Gamma \ b_1 \ b_2 \rightarrow \text{EQC } \Gamma \ a_1 \ b_1 \rightarrow \text{EQC } \Gamma \ a_2 \ b_2 \rightarrow \text{Set} \end{aligned}$$
- an inductive data type **data**  $\_ \vdash \_ \rhd \_$   $(\Gamma : Cx) : \forall \{n\} (T : \text{Typeover } n \ \Gamma) (t : \text{Section } T) \rightarrow \text{Set}_1$

The formalisation is available online at <https://github.com/radams78/Equality2>.

**Related Work** An earlier version of this system was presented in [2]. In this talk, we also give semantics to this system in Agda’s type theory extended with a native type of groupoids, and show how the syntax and semantics are formalised in Agda.

Our system is closely related to the system PHOML (Predicative Higher-Order Minimal Logic) presented in [1]. The system  $\lambda \simeq_2$  can be seen as an extension of PHOML with groupoids, and with a univalent equality for both sets and groupoids.

Cubical type theory [3, 4] has a very similar motivation to this work, and also offers a type theory with univalence and a computational interpretation. One difference with our system is that the following equations hold judgementally:

**TODO**

The corresponding equations in cubical type theory would be  $\text{transp}^i A a = a$  where  $i$  does not occur in  $A$ , and  $\text{transp}^j B (\text{transp}^i A a) = \text{transp}^i (\text{comp}^j U [(i = 0) \mapsto A[i := 0], (i = 1) \mapsto B]) A a$ . In cubical type theory, these equations do hold up to definitional equality for all terms  $a$ . They hold up to definitional equality when  $a$  is a canonical object, and up to propositional equality in general.
