A Type Theory with Native Homotopy Universes

Robin Adams[1] and Andrew Polonsky[2]

We present a type theory $\lambda \simeq_2$ with an extensional equality relation; that is, the universe of types is closed by reflection into it of the logical relation defined by induction on the structure of types.

The type system has four universes:

- The trivial universe $\mathbf{1}$, with one type $\top$ that has one object $*$.
- The universe **Prop** of *propositions*. An object of **Prop** is called a *proposition*, and the objects of a proposition are called *proofs*.
- The universe **Set** of *sets*.
- The universe **Groupoid** of *groupoids*.

For each universe U, we have an associated relation of equality between the universes $\simeq$, and between objects of the universes $\sim$, with associated rules of deduction:

$$\frac{A : U \quad B : U}{A \simeq B : U} \qquad \frac{a : A \quad e : A \simeq B \quad b : B}{a \sim_e b : U^-}$$

where U^- is the universe one dimension below U. Thus:

- Given two propositions ϕ and ψ, we have the proposition $\phi \simeq \psi$ which denotes the proposition 'ϕ if and only if ψ'. If $\delta : \phi$, $\epsilon : \psi$ and $\chi : \phi \simeq \psi$, then $\delta \sim_\chi \epsilon = * : \mathbf{1}$. (*Cf* In homotopy type theory, any two objects of a proposition are equal.)
- Given two sets A and B, we have the set $A \simeq B$, which denotes the set of all bijections between A and B. Given $a : A$, $f : A \simeq B$ and $b : B$, we have the proposition $a \sim_f b : \mathbf{Prop}$, which denotes that a is mapped to b by the bijection f.
- Given two groupoids G and H, we have the groupoid $G \simeq H$, which denotes the groupoid of all groupoid isomorphisms between G and H. Given $g : G$, $\phi : G \simeq H$ and $h : H$, we have the set $g \sim_\phi h : \mathbf{Set}$, which can be thought of as the set of all paths between $\phi(g)$ and h in H.

We have reflexivity provided by the following typing rules:

$$\frac{1_A : A \simeq A}{A : U} \qquad \frac{r_a : a \sim_{1_A} a}{a : A}$$

The relation $\sim_{1_A}$ thus behaves like an equality relation on each type A.

Each universe is itself an object of the next universe:

$$\mathbf{1} : \mathbf{Prop} : \mathbf{Set} : \mathbf{Groupoid}$$

and we have the following definitional equalities:

$$\phi \sim_{1_{\mathbf{Prop}}} \psi \stackrel{\text{def}}{=} \phi \simeq \psi, \quad A \sim_{1_{\mathbf{Set}}} B \stackrel{\text{def}}{=} A \simeq B$$

The following computation rules also hold in $\lambda\simeq_2$.

TODO

We therefore note the following features of $\lambda\simeq_2$:

- Univalence holds definitionally — an equality between types $A \simeq B$ is exactly the type of equivalences between A and B.
- Transport respects reflexivity and composition definitionally.

This type theory has been formalised in Agda, using the method of the system `Kipling` from McBride [1].

The formalisation is available online at https://github.com/radams78/Equality2.
