A Type Theory with Native Homotopy Universes

Robin Adams¹ and Andrew Polonsky²

¹ Universitetet i Bergen

We present a type theory called $\lambda \simeq_2$ with an extensional equality relation; that is, the universe of types is closed by reflection into it of the logical relation defined by induction on the structure of types.

The type system has three universes:

- The universe **Prop** of *propositions*. An object of **Prop** is called a *proposition*, and the objects of a proposition are called *proofs*. There is a proposition 1, which has a unique proof *.
- The universe **Set** of *sets*.
- The universe **Groupoid** of *groupoids*.

The system has been designed in such a way that it should be straightforward to extend the system with three, four, ...dimensions.

For each universe U, we have an associated relation of equality between U-types \simeq , and between objects of U-equal types \sim . The associated rules of deduction are:

$$\frac{A:U\quad B:U}{A\simeq B:U} \qquad \frac{a:A\quad e:A\simeq B\quad b:B}{a\sim_e b:U^-}$$

where U^- is the universe one dimension below U. Thus:

- Given two propositions ϕ and ψ , we have the proposition $\phi \simeq \psi$ which denotes the proposition ' ϕ if and only if ψ '. If $\delta : \phi$, $\epsilon : \psi$ and $\chi : \phi \simeq \psi$, then $\delta \sim_{\chi} \epsilon = 1$. (Cf In homotopy type theory, any two objects of a proposition are equal.)
- Given two sets A and B, we have the set $A \simeq B$, which denotes the set of all bijections between A and B. Given a:A, $f:A \simeq B$ and b:B, we have the proposition $a \sim_f b:$ **Prop**, which denotes that a is mapped to b by the bijection f.
- Given two groupoids G and H, we have the groupoid $G \simeq H$, which denotes the groupoid of all groupoid equivalences between G and H. Given g:G, $\phi:G\simeq H$ and h:H, we have the set $g\sim_{\phi} h:\mathbf{Set}$, which can be thought of as the set of all paths between $\phi(g)$ and h in H.

The introduction and elimination rules for \simeq ensure that $A \simeq B$ is the type of equivalences between A and B.

² University Paris Diderot

Each universe is itself an object of the next universe; thus $\mathbf{1}: \mathbf{Prop}: \mathbf{Set}: \mathbf{Groupoid}$. We also have the following definitional equalities: $\phi \sim_{\mathbf{1prop}} \psi \stackrel{\mathrm{def}}{=} \phi \simeq \psi, \ A \sim_{\mathbf{1set}} B \stackrel{\mathrm{def}}{=} A \simeq B$. As well as the normal operation of substitution, we have an operation of path substitution:

$$\frac{\Gamma, x: A \vdash b: B \quad \Gamma \vdash e: a \sim_{1_A} a'}{\Gamma \vdash b[x//e]: b[x/a] =_{B[x//e]} b[x/a']}$$

The system $\lambda \simeq_2$ enjoys the following properties. Univalence holds definitionally; that is, an equality between types $A \simeq B$ is exactly (definitionally) the type of equivalences between A and B. Also, transport respects reflexivity and composition definitionally.

This type theory has been formalised in Agda, using the method of the system Kipling from McBride [5]. The method ensures that, if s and t are definitionally equal expressions in $\lambda \simeq_2$, then $\llbracket s \rrbracket$ and $\llbracket t \rrbracket$ are definitionally equal objects in Agda. We interpret each context with a groupoid in Agda; that is, we define a type

```
data Cx : Set<sub>1</sub>
of contexts, and functions
      [\_]C:Cx\to Set_1
     \overline{\mathsf{EQC}} : \forall \ \Gamma \to [\ \Gamma\ ]\mathsf{C} \to [\ \Gamma\ ]\mathsf{C} \to \mathsf{Set}
     \mathsf{EQC}_2: \forall \{\Gamma\} \{a_1 \ a_2 \ b_1 \ b_2: [\Gamma] \cap \mathsf{C}\} \rightarrow
          \mathsf{EQC}\;\Gamma\;a_1\;a_2\to\mathsf{EQC}\;\Gamma\;b_1\;b_2\to\mathsf{EQC}\;\Gamma\;a_1\;b_1\to\mathsf{EQC}\;\Gamma\;a_2\;b_2\to\mathsf{Set}
The formalisation is available online at https://github.com/radams78/Equality2.
```

Related Work An earlier version of this system was presented in [2]. In this talk, we also give semantics to this system in Agda's type theory extended with a native type of groupoids, and show how the syntax and semantics are formalised in Agda.

Our system is closely related to the system PHOML (Predicative Higher-Order Minimal Logic) presented in [1]. The system $\lambda \simeq_2$ can be seen as an extension of PHOML with groupoids, and with a univalent equality for both sets and groupoids.

Cubical type theory [3, 4] has a very similar motivation to this work, and also offers a type theory with univalence and a computational interpretation. One difference with our system is that transport across the identity path is identity, and transport across $p \bullet q$ is the composition of transport across p with transport across q, up to definitional equality. In cubical type theory, these equations only hold up to propositional equality.
